

Mike Barlotta

Spring Framework Part 3

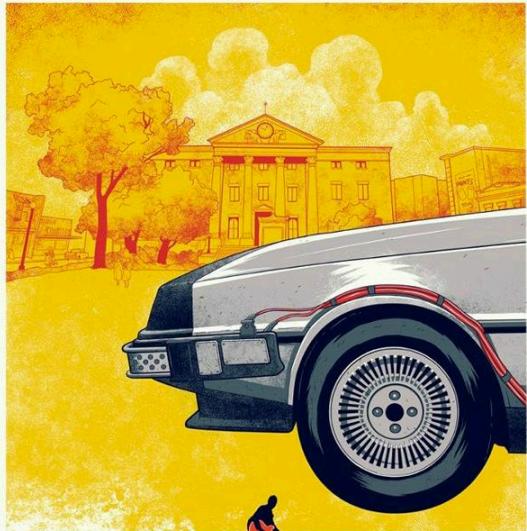

What is Spring?

- Dependency Injection framework
 - introduced in 2002 in Rod Johnson's book
 - open sourced in 2003
 - Spring 1.0 available in 2004
- Ecosystem of Capabilities
 - Spring MVC
 - Spring Data
 - Spring Batch
 - Spring Integration
 - Spring Cloud

Where we have been

What is a IoC/DI container & why use them?

Where we have been

Decides when to
create objects &
which type of
dependency the
client object will **use**

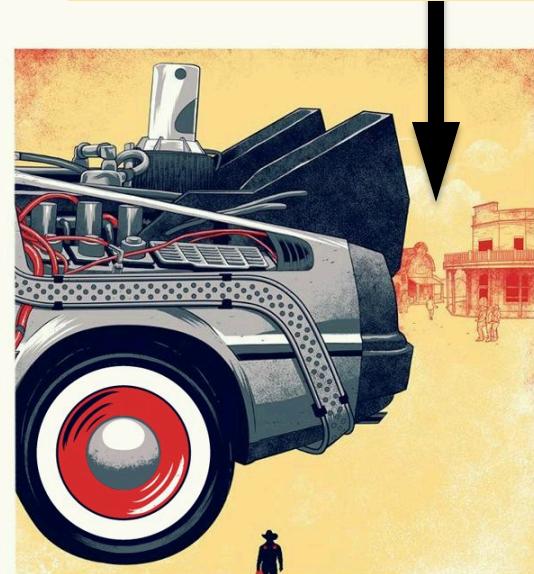

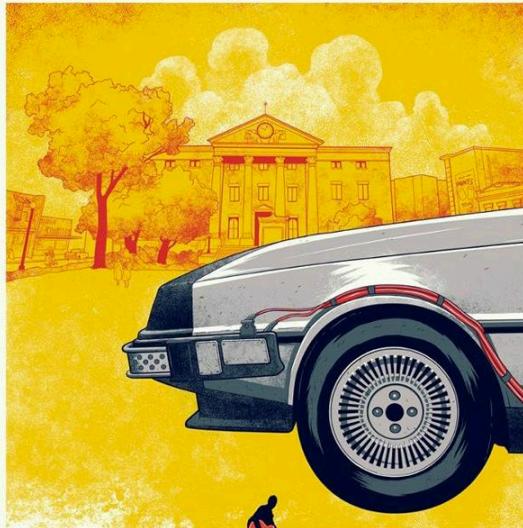

What is a IoC/DI container & why use them?

BeanFactory vs ApplicationContext & configuration options

Where we are going

Decides the **number** of instances & **lifecycle** of the client object and dependent objects

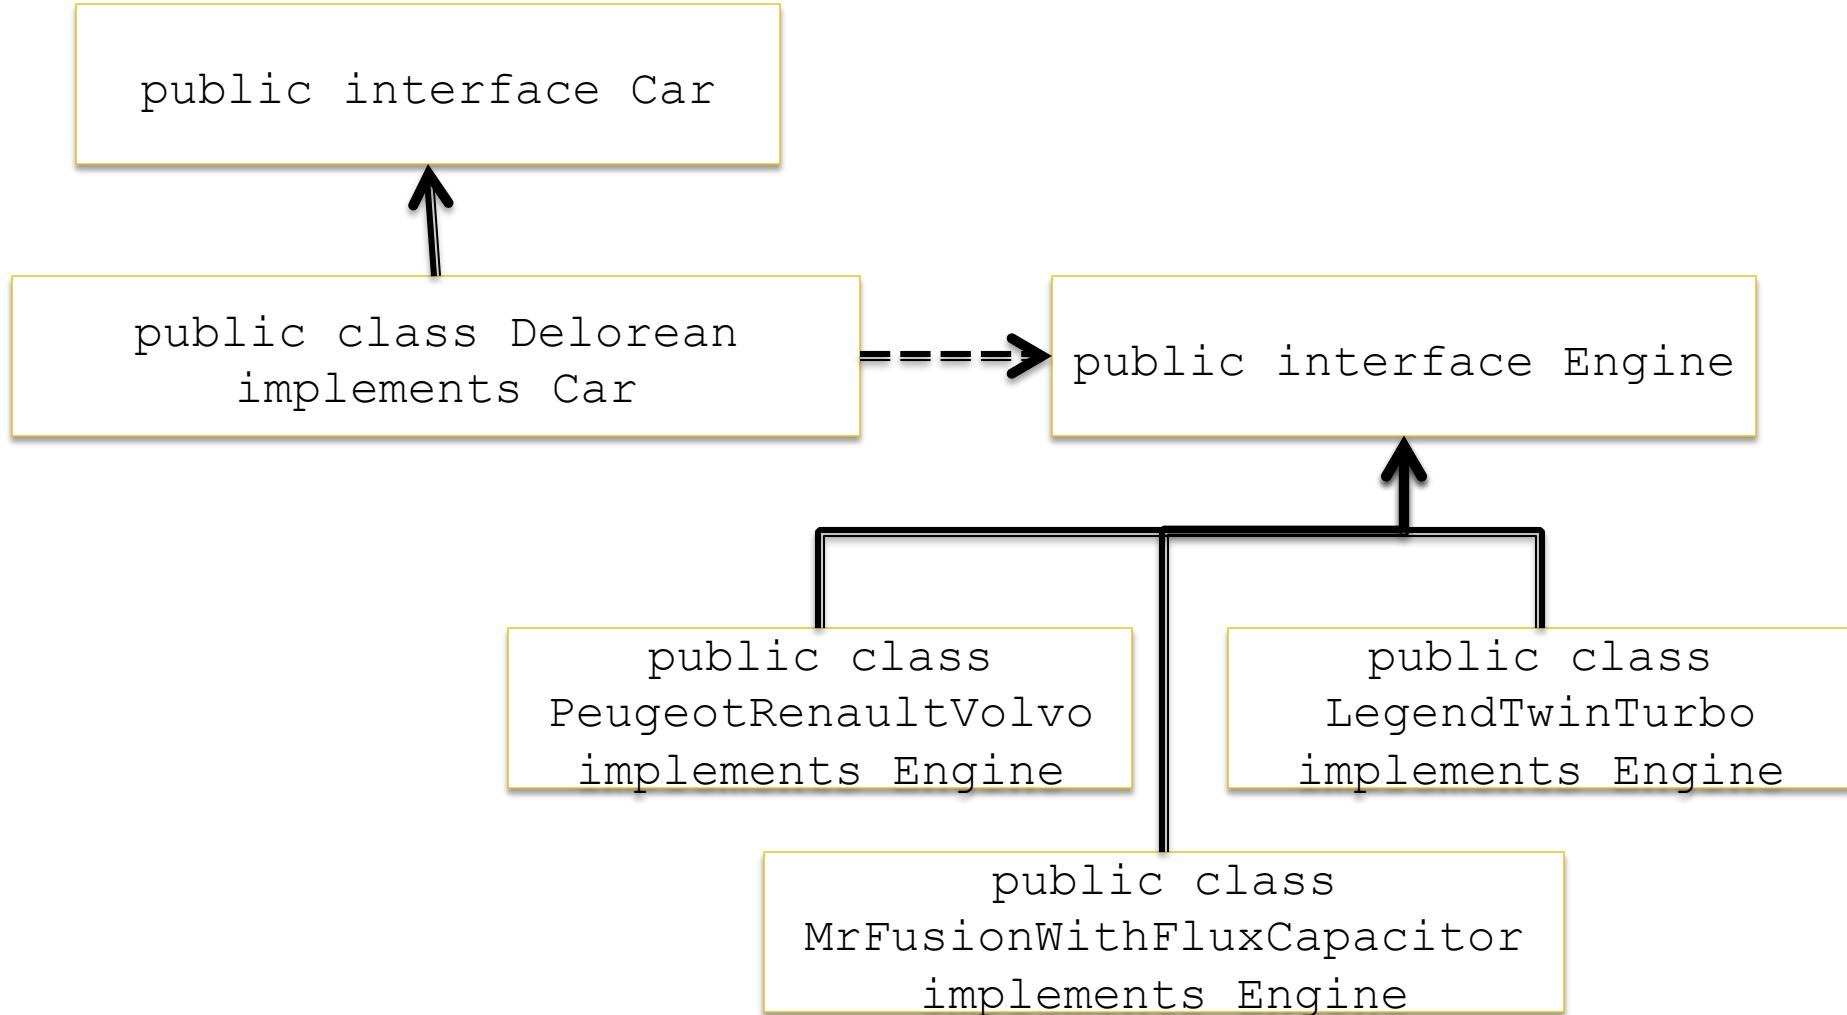

What is a IoC/DI container & why use them?

BeanFactory vs ApplicationContext & configuration options

Using Delorean and Engine Design

DI + DIP

How many instances should be created by the Spring container?

Scope: Singleton

- Default scope for all beans is singleton.
 - Only one instance of the bean is created by the container (*for each bean name*) & shared

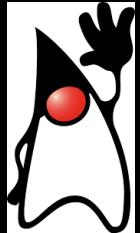

Scope: Prototype

- Container creates more than one instance
 - New instance of the bean is created by the container each time one is requested (via call to getBean or injection point)

Mixing Scopes

What happens when a prototype bean is injected into a singleton bean instance?

What happens when a singleton bean is injected into a prototype bean instance?

What happens to that bean when Spring build it?

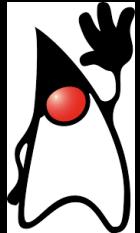

Customizing Initialization & Destruction of a Bean

```
@Configuration  
public class DeloreanConfig {  
  
    @Bean(name="delorean",  
          initMethod = "customInit",  
          destroyMethod = "customDestroy")  
    @Scope(value = "singleton")  
    public Car buildDelorean(Engine engine) {  
  
        ...  
    }  
}
```

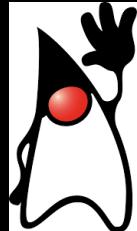

```
public class Delorean  
    implements Car,  
    InitializingBean,  
    BeanNameAware,  
    ApplicationContextAware,  
    DisposableBean
```

Getting that Bean ready to use

1. Create the Bean
2. Inject the dependencies
3. BeanNameAware interface
4. BeanFactoryAware interface
5. ApplicationContextAware interface
6. --
7. @PostConstruct
8. InitializingBean interface
9. custom init method via @Bean(initMethod)
10. --
11. @PreDestroy
12. DisposableBean interface
13. Custom destroy method via @Bean(destroyMethod)

Scope and the Bean's lifecycle

Singleton Scope

- Since there is only one instance the lifecycle is only processed once for the bean

Prototype Scope

- Each instance of the bean goes through the lifecycle
- *No destruction phase of the lifecycle*

BeanPostProcessor

What are they for?

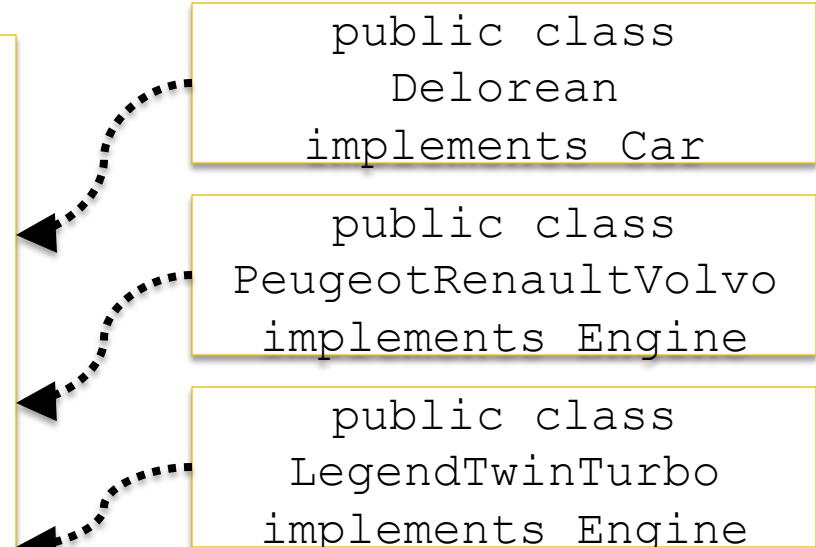

- BeanPostProcessor beans are commonly used to extend Spring container.
- Examples in Spring
 - CommonAnnotationBeanPostProcessor handles the @PostConstruct and @PreDestroy annotations on beans
 - RequiredAnnotationBeanPostProcessor handles the @Require annotation on beans

BeanPostProcessor interface

- An ApplicationContext automatically detects any beans in @Configuration that implement the interface.
- BeanPostProcessor beans and their dependencies are instantiated *before* all other beans. But it can't use @Value
- BeanPostProcessor beans are used to process all other beans in the container.

Adding BeanPostProcessor(s)

```
public class  
BackToFuturePostProcessor  
implements BeanPostProcessor  
  
postProcessBeforeInitialization()  
  
postProcessAfterInitialization()
```

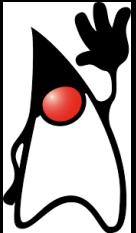

- **BeanPostProcessor** beans are used to process all other beans in the container.

ApplicationContext registers the BPP...

```
appContext = new  
AnnotationConfigApplicationContext();  
  
appContext.register(DeloreanConfig.class,...);  
appContext.refresh();
```

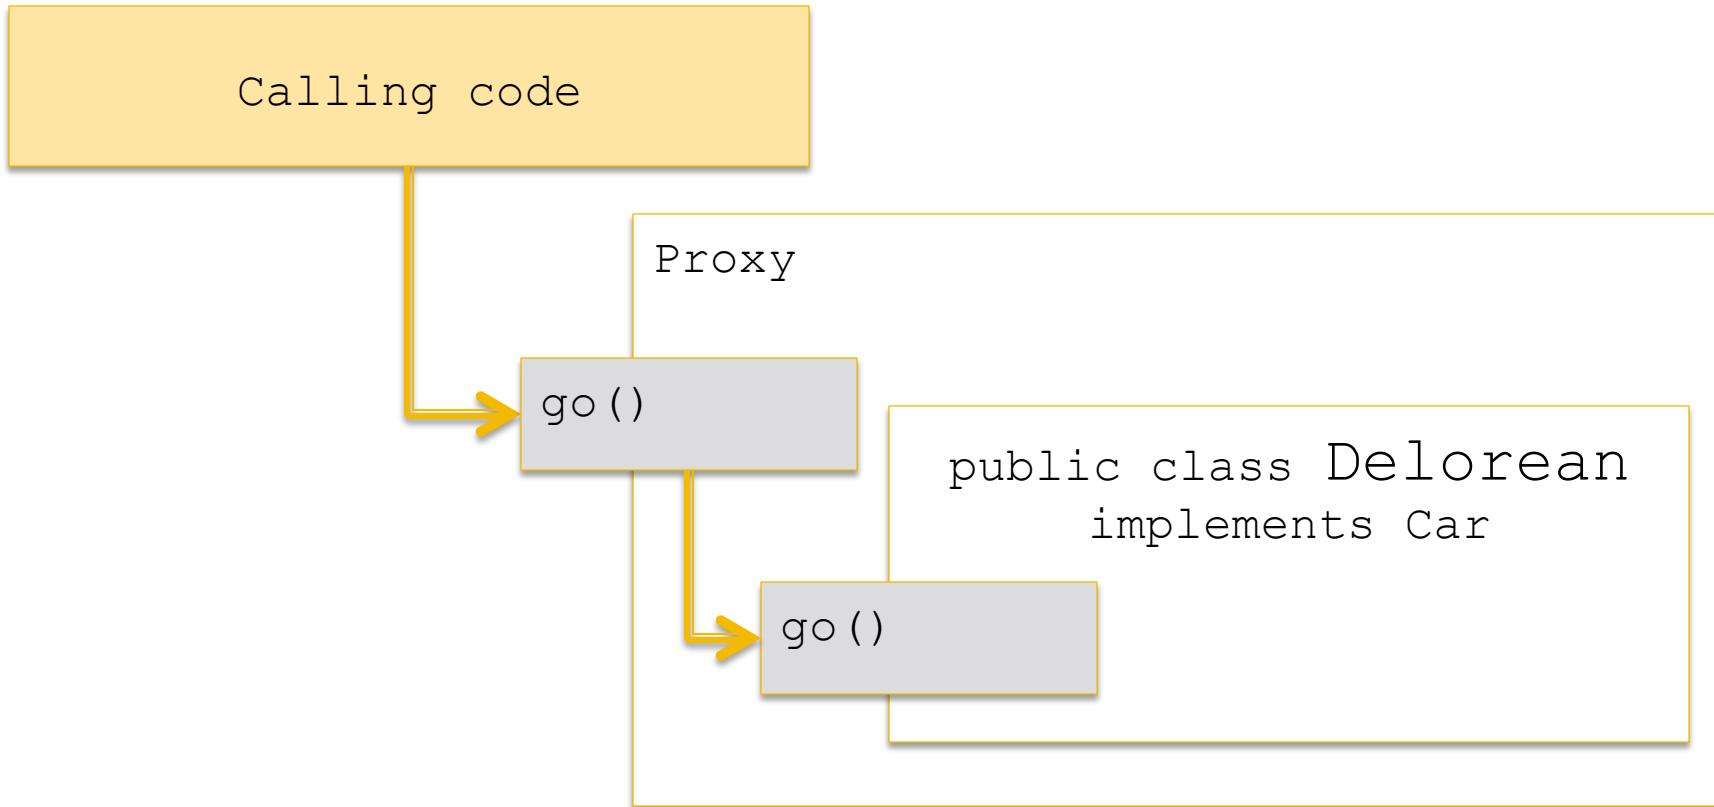

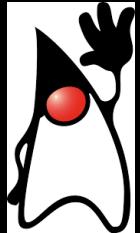

```
public class AbstractApplicationContext ...  
@Override  
public void refresh() ... {  
    ...  
    registerBeanPostProcessors(beanFactory);
```

Where do BPP fit in ?

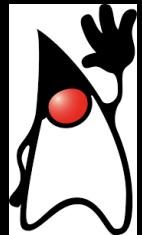

1. Create the Bean
2. Inject dependencies
3. BeanNameAware interface
4. BeanFactoryAware interface
5. ApplicationContextAware interface
6. **BeanPostProcessor.postProcessBeforeInitialization**
7. @PostConstruct
8. InitializingBean interface
9. custom init method via @Bean(initMethod)
10. **BeanPostProcessor.postProcessAfterInitialization**
11. @PreDestroy
12. DisposableBean interface
13. Custom destroy method via @Bean(destroyMethod)

Timing the Car.go method

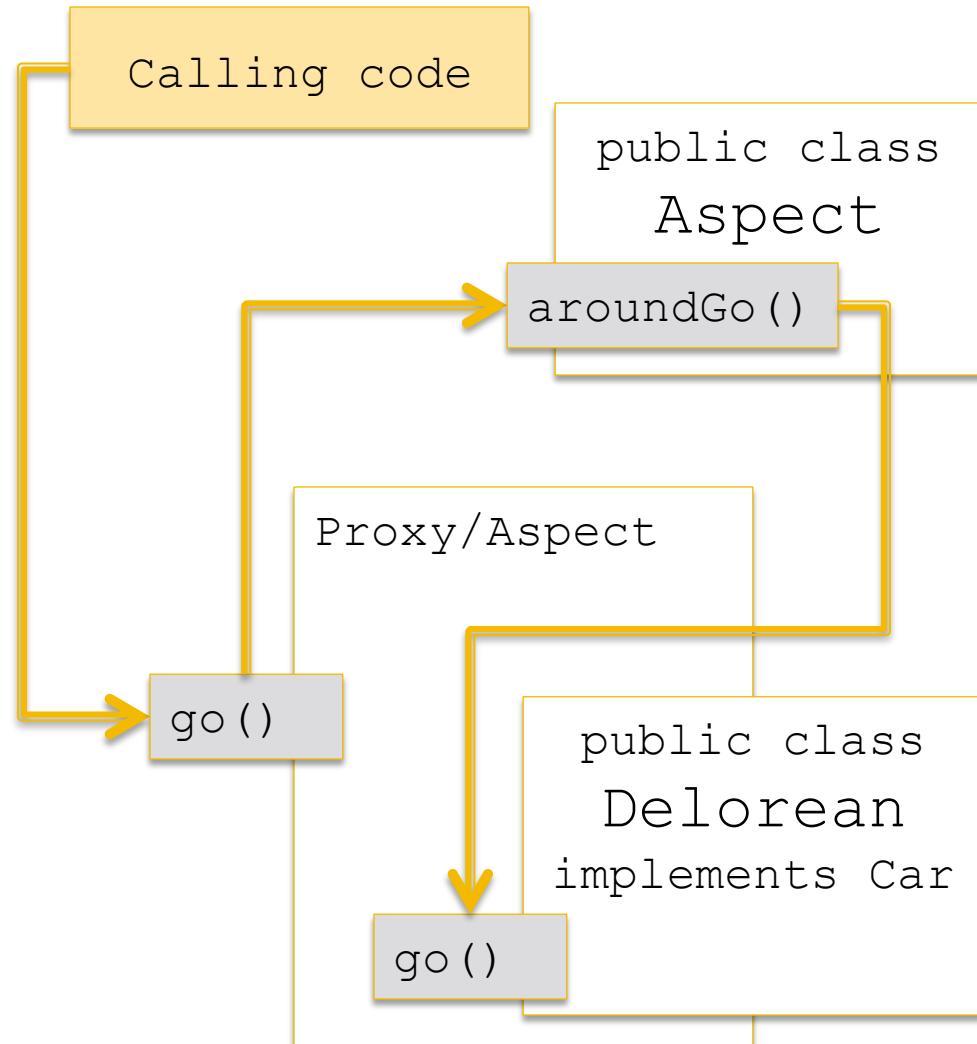

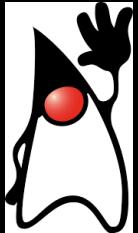

BeanPostProcessor used to wrap instances of Car with a Timer if they are annotated with @BackToFuture.

Spring AOP

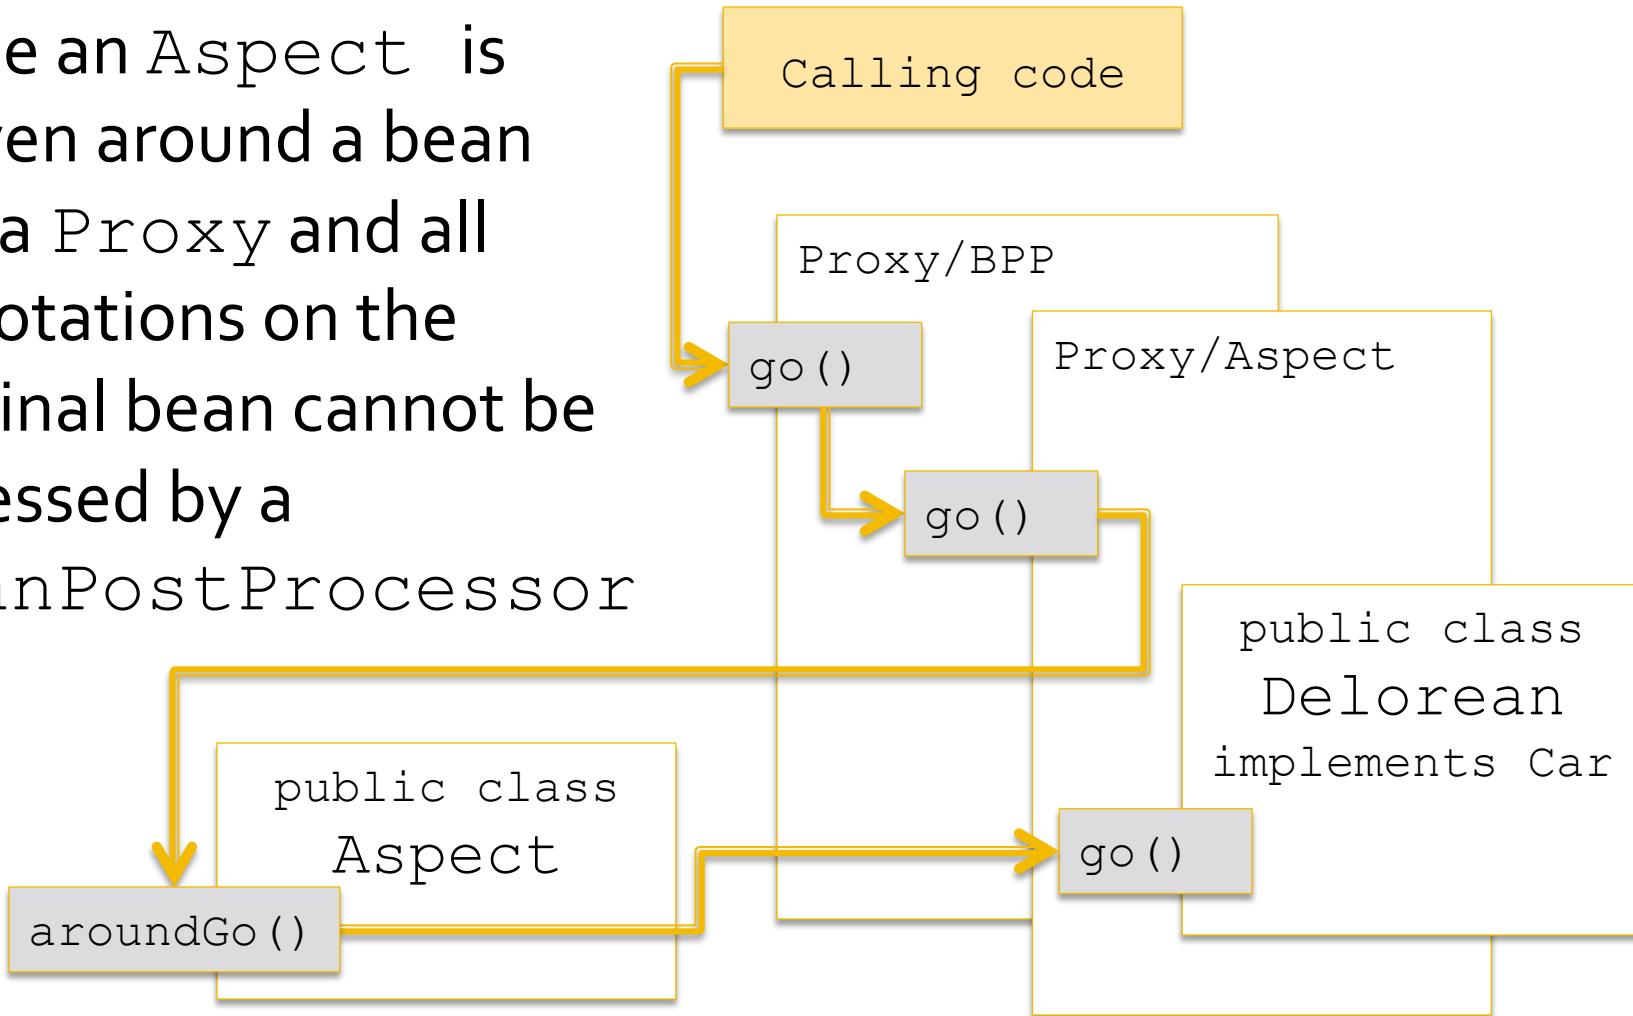

- Aspects are written using POJOs
 - Similar to writing a BeanPostProcessor
- Aspects are woven around managed beans using dynamic proxies
- Limited to method interception
 - Need to use AspectJ if need more than this

BPP and AOP

Once an Aspect is woven around a bean it is a Proxy and all annotations on the original bean cannot be accessed by a BeanPostProcessor

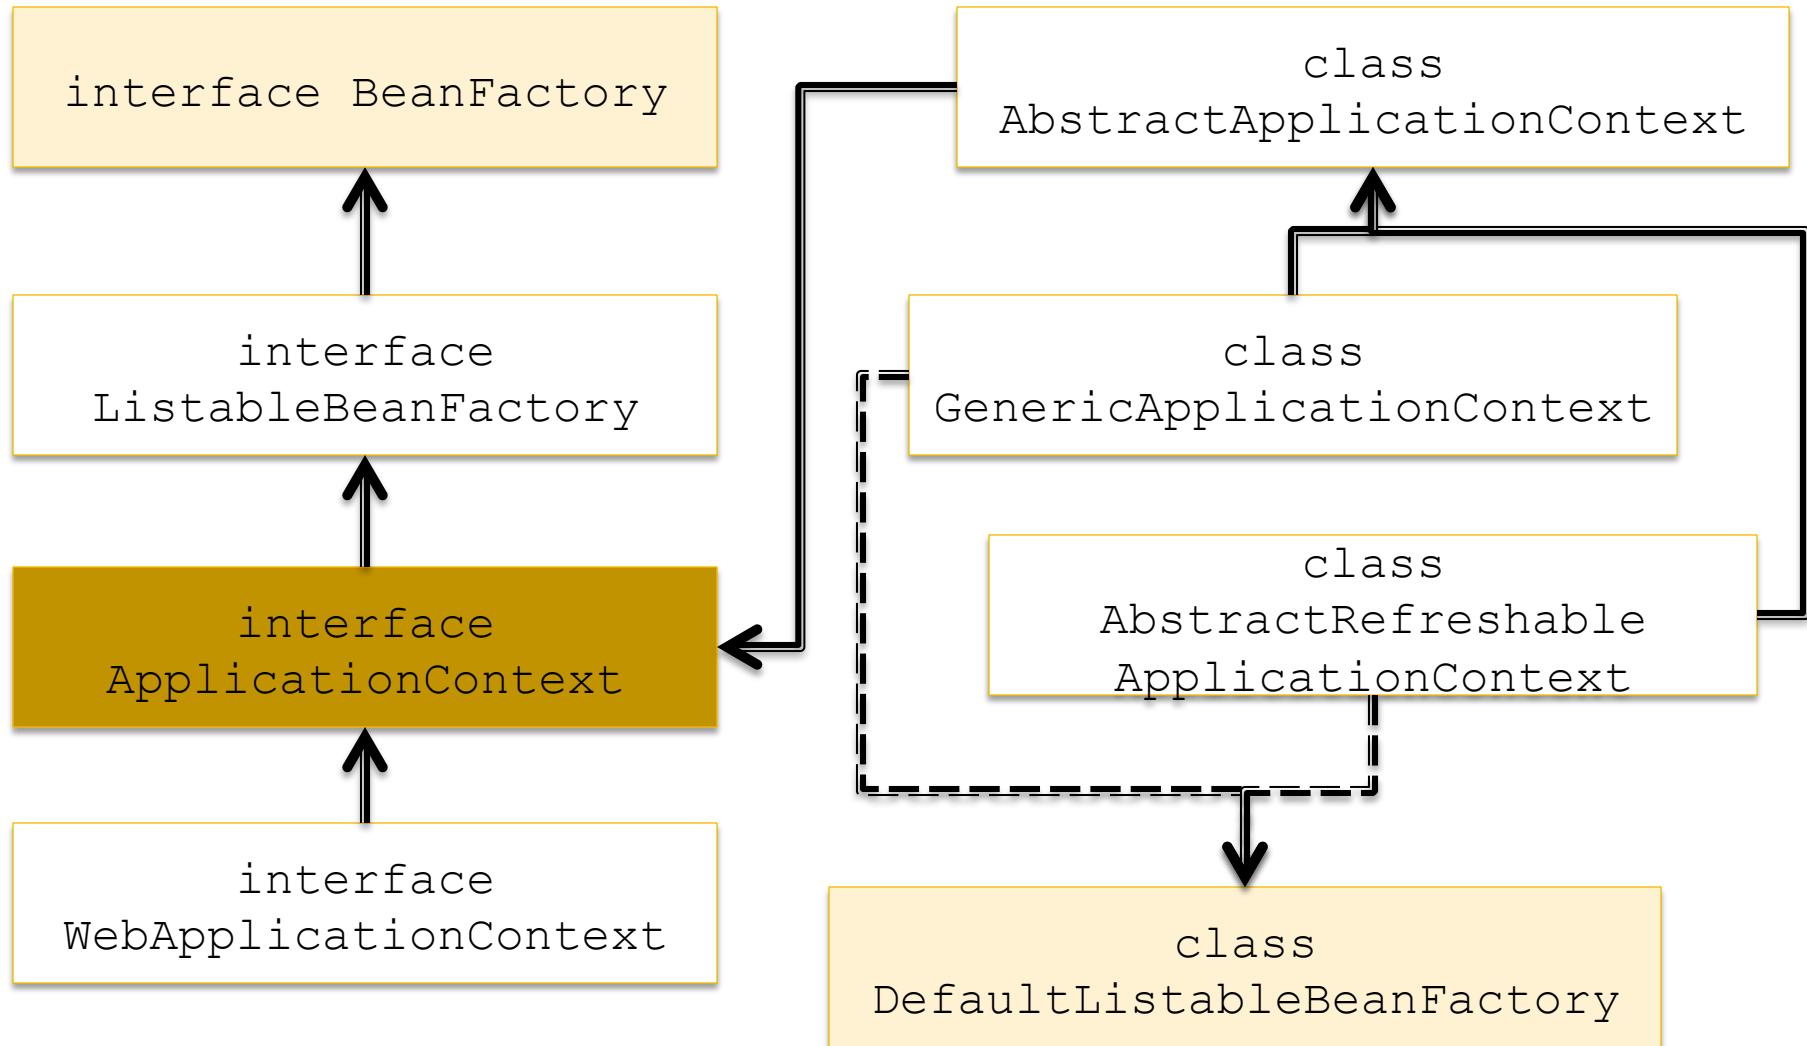

Q & A

ApplicationContext options

- ▼  ApplicationContext
- ▼  ConfigurableApplicationContext
- ▼   AbstractApplicationContext
- ▼   AbstractRefreshableApplicationContext
- ▼   AbstractRefreshableConfigApplicationContext
- ▼   AbstractRefreshableWebApplicationContext
 -  AnnotationConfigWebApplicationContext
 -  GroovyWebApplicationContext
 -  XmlWebApplicationContext
- ▼   AbstractXmlApplicationContext
 -  ClassPathXmlApplicationContext
 -  FileSystemXmlApplicationContext
-  GenericApplicationContext
-   AnnotationConfigApplicationContext

ApplicationContext uses DefaultListableBeanFactory

DefaultListableBeanFactory
